

## 2.10.3 Link Facts

The Linux file system supports a special file type called a link file. Link files don't actually contain any content. Instead, they are redirectors that point you to a different file or directory in the file system.

This lesson covers the following topics:

- Link file types
- Create links

### Link File Types

Links are files that point to another file. Linux uses two types of links:

Type	Description
Hard link	<p>A hard link is a duplicate entry in the file system that points to a specific piece of data on the disk drive. With a hard link:</p> <ul style="list-style-type: none"><li>• Duplicate file inodes are used. The inode specifies where a file's data physically exists on a disk. With a hard link, the link file and the original file both share the same inode.</li></ul> <div> The <b>ls -i</b> command displays the inodes for the files and directories in a directory.</div> <ul style="list-style-type: none"><li>• The data stored in the link file is exactly the same as the data in the original file.</li><li>• The data is preserved within the link file, even if the original file is deleted.</li><li>• In the output from the <b>ls -a</b> command, a hyphen is used as the first character in the permission string, which is the same character used for normal files (for example, -rwxr-xr-x).</li></ul>
Symbolic link	<p>A symbolic link (also known as a soft link) is a file that points to another file in the file system. A symbolic link is similar to shortcuts in the Windows OS. With a symbolic link:</p> <ul style="list-style-type: none"><li>• Separate inodes are used. The link file has an inode that is distinct from the inode of the file being pointed to.</li><li>• The output from the <b>ls -a</b> command:<ul style="list-style-type: none"><li>◦ A lower-case L (l) is used as the first character in the permission string (for example, lrwxrwxrwx indicates a symbolic link).</li><li>◦ The -&gt; character sequence follows the file name, which is followed by the file that the link points to.</li></ul></li></ul>

## Create Links

The following commands are used to create hard links and symbolic links:

Command	Function	Examples
<b>ln</b> <i>[source]</i> <i>[link_name]</i>	Creates links. <ul style="list-style-type: none"> <li>• <b>ln -s</b> creates a symbolic link to a file.</li> <li>• <b>ln</b> (with no options) creates a hard link between files.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>ln /home/jsmith/project1 /home/edunford/project1</b> creates a hard link to /home/jsmith/project1 in /home/edunford/.</li> <li>• <b>ln -s /home/jsmith/project1 /home/edunford/project1</b> creates a symbolic link named /home/edunford/project1 ln that points to /home/jsmith/project1.</li> <li>• <b>ln -s /home/jsmith/project1 /home/edunford/project1 ln</b> creates a symbolic link named /home/edunford/project1 ln that points to /home/jsmith/project1.</li> </ul>
<b>cp</b> <i>[source]</i> <i>[link_name]</i>	Copies files and creates links. <ul style="list-style-type: none"> <li>• <b>cp -l</b> creates hard links rather than copying the files.</li> <li>• <b>cp -s</b> creates symbolic links rather than copying the files.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>cp -l /home/jed/fil1 /home/esam/proj1</b> creates an exact copy of /home/jed/fil1 in /home/esam/.</li> <li>• <b>cp -s /home/mkon/text /home/ytew/text ln</b> creates a symbolic link named /home/ytew/text ln that points to /home/mkon/text.</li> </ul>
<b>unlink</b> <i>[link_name]</i>	Removes both symbolic links and hard links.	<ul style="list-style-type: none"> <li>• <b>unlink project1 ln</b> removes the project1 ln link that point to /home/jsmith/project1.</li> </ul>
