Which system component verifies the hardware and passes control of the computer to the boot loader?

- OS kernel
- Init
- **CMOS**
- BIOS

Explanation

The BIOS is responsible for verifying system hardware, reading settings from the CMOS, detecting hardware changes, and passing control of the system to the boot loader.

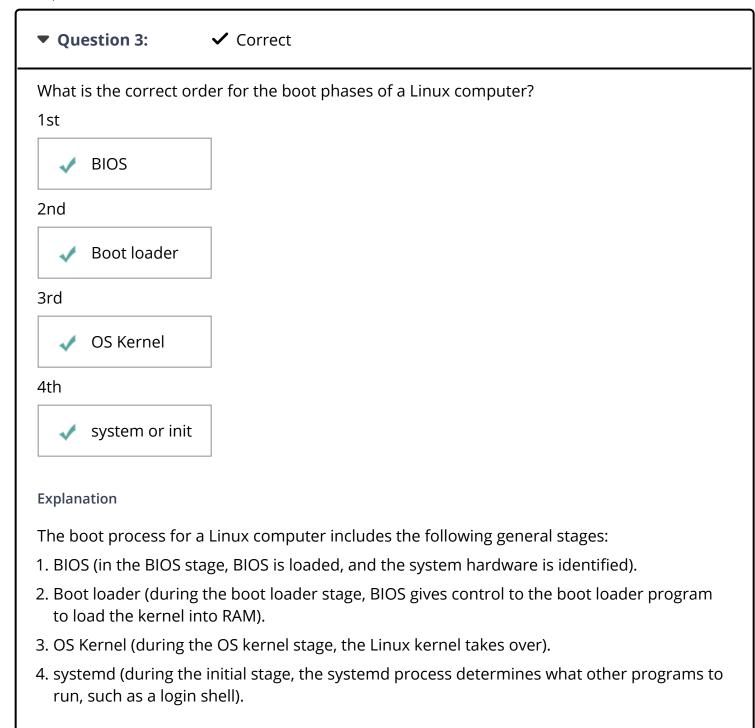

The boot process for a Linux computer includes the following general stages:

- 1. BIOS (in the BIOS stage, BIOS is loaded, and the system hardware is identified).
- 2. Boot loader (during the boot loader stage, BIOS gives control to the boot loader program to load the kernel into RAM).
- 3. OS Kernel (during the OS kernel stage, the Linux kernel takes over).
- 4. Init (during the Init stage, the initial [init or system] process determines which other programs to run, such as a login shell).

In which boot process stage is the root partition mounted?

- systemd
- BIOS
- Boot loader
- → OS kernel

Explanation

The OS kernel stage mounts the root partition. During this stage, the Linux kernel:

- 1. Resides in the /boot directory.
- 2. Initializes the hardware on the system.
- 3. Locates and loads the initrd script to access the linuxrc program, which configures the operating system.
- 4. Dismounts and erases the RAM disk image (initrd image).
- 5. Looks for new hardware and loads the drivers.
- 6. Mounts the root partition.
- 7. Loads and executes the initial process, such as SysV init or systemd on newer Linux distributions.

The boot process for a Linux computer includes the following general stages:

- 1. BIOS (in the BIOS stage, BIOS is loaded and the system hardware is identified).
- 2. Boot loader (during the boot loader stage, BIOS gives control to the boot loader program to load the kernel into RAM).
- 3. OS Kernel (during the OS kernel stage, the Linux kernel takes over).
- 4. systemd (during the initial stage, the systemd process determines what other programs to run, such as a login shell or configuration files).

▼ Question 5:	✓ Correct
	with more than one Linux operating system installed. During the system's which component loads a splash screen, allowing you to choose which you want to run?
BIOS	
The initial	al program
→ The seco	ndary boot loader
The prim	ary boot loader
Explanation	

11/15/22, 6:36 PM

The secondary boot loader provides a splash screen that allows you to choose which operating system you want to load. This occurs in the *boot loader* stage of the boot process. Specifically, during the boot loader stage, the following steps take place:

- 1. BIOS searches the boot sector which contains a Master Boot Record (MBR).
- 2. BIOS loads the primary boot loader code from the MBR.
- 3. The primary boot loader takes one of two actions:
 - Examines the partition table marked as bootable and then loads the boot sector from that partition. This boot sector contains a secondary boot loader, which locates an OS kernel.
 - Locates an OS kernel directly, without using a secondary boot loader.
- 4. When the secondary boot loader is in RAM and executing, a splash screen is commonly displayed, and an optional initial RAM disk, initrd image, is loaded into memory. The initrd image:
 - Has root permissions and can be used to access the actual /root file system regardless of whether it exists on the local computer or an external device. Without the permissions, the computer could not access the file systems without being able to read information that only exists on those file systems.
 - Is used to mount the actual file system and load the kernel into RAM.
- 5. With the images ready, the secondary boot loader invokes the kernel image.

The BIOS is responsible for verifying system hardware, reading settings from the CMOS, detecting hardware changes, and passing control of the system to the boot loader. The initial (init or systemd) process is the first process on the Linux system to run. Init determines which other programs to run, such as a SysV init login shell or systemd configuration files.

Which of the following has a process ID (PID) of 1?

- The BIOS
- The initial process
 - The boot loader
 - The OS kernel

Explanation

The initial process have the process ID (PID) of 1 because it is the first process to run on the system. On a SysV init Linux system, the name of the initial process is init. On a systemd Linux system, the initial process is named systemd.

The BIOS, boot loader, and OS kernel do not receive PIDs.

✓ Correct Question 7:

Which component is responsible for loading and executing the initial process?

- initrd image
- primary boot loader
- OS kernel
 - **BIOS**

Explanation

The OS kernel stage loads and executes the initial (init) process. During this stage, the Linux kernel:

- 1. Resides in the /boot directory.
- 2. Initializes the hardware on the system.
- 3. Locates and loads the initrd script to access the linuxrc program which configures the operating system.
- 4. Dismounts and erases the RAM disk image (initrd image).
- 5. Looks for new hardware and loads the drivers.
- 6. Mounts the root partition.
- 7. Loads and executes the initial process (init or systemd).

The BIOS is responsible for verifying system hardware, reading settings from the CMOS, detecting hardware changes, and passing control of the system to the boot loader. The initrol image is used to mount the actual file system and loads the kernel into RAM. The primary boot loader takes one of two actions:

- Examines the partition table marked as bootable and then loads the boot sector from that partition. This boot sector contains a secondary boot loader, which locates an OS kernel.
- Locates an OS kernel directly, without using a secondary boot loader.
